# Regression Analysis Project $\mid$ Spring 2010 

## Regression analysis of heart disease (Cardiovascular Health)

## Introduction

The purpose of this project is to build a regression equation to explain the variation in heart disease mortality rate among the US states. A few factors which may affect the heart disease rate are taken into consideration and tested in my model. These factors include: Obesity, Smoking, Physical activities, hypertension and poverty. All the calculations were performed in the attached excel file (RA_Xiaofeng Qian_spring2010_Heart disease.xls).

## Model Construction

## 1. Build the original linear regression equation.

My original equation is displayed as follow:
$\mathrm{Y}_{\mathrm{i}}=\beta_{0}+\beta_{1} \mathrm{X}_{1 \mathrm{i}}+\beta_{2} \mathrm{X}_{2 \mathrm{i}}+\beta_{3} \mathrm{X}_{3 \mathrm{i}}+\beta_{4} \mathrm{X}_{4 \mathrm{i}}+\beta_{5} \mathrm{X}_{5 \mathrm{i}}+\varepsilon_{\mathrm{i}}$
where,
Y is the heart disease death rate / 100000 by state (data obtained from
http://www.statemaster.com/ ).
$\mathrm{X}_{1}$ is the obesity rate by state (data obtained from http://www.statemaster.com/).
$\mathrm{X}_{2}$ is the percentage of smokers by state (data obtained from
http://www.statemaster.com/ ).
$\mathrm{X}_{3}$ is the No Leisure-Time Physical Activity rate by state (data obtained from http://www.cdc.gov/).
$\mathrm{X}_{4}$ is the hypertension rate by state (data obtained from http://healthyamericans.org/).
$\mathrm{X}_{5}$ is the percentage below poverty by state (data obtained from http://www.statemaster.com/ ).

The original model with all the variables were calculated in the attached Excel Spreadsheet and shown in Table 1. From Table 1, I found the regression model has strong statistics on R square ( 0.766042 ), adjust R square ( 0.740047 ) and $F$ statistics (Significance of $F=3.8 \mathrm{E}-13$ ). However, I noticed a few problems in the preliminary results. First of all, the variable of the obesity rate has a very poor $t$ statistics ( 0.743493 ) and a high $P$-Value ( 0.461047 ) which is a big surprising to me. Because the obesity rate is thought to be very close to the occurrence of the heart disease from medical research and experience. Secondary, the standard errors for most of the independent variables are

# Regression Analysis Project Spring 2010 

By Xiaofeng Qian too high. All these indicate there must be multicollinearity among the independent variables.

Table 1. Original regression Statistics summary

| Regression Statistics |  |
| :---: | :---: |
| Multiple R | 0.875238 |
| R Square | 0.766042 |
| Adjusted R square | 0.740047 |
| Standard Error | 19.22071 |
| Observations | 51 |

ANOVA

|  | $d f$ | SS | MS | $F$ | $F$ <br> Significance |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Regression | 5 | 54433.54 | 10886.71 | 29.47 | $3.80 \mathrm{E}-13$ |
| Residual | 45 | 16624.61 | 369.43 |  |  |
| Total | 50 | 71058.15 |  |  |  |

|  | Coefficients | Standard |  | Lower |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | $t$ Stat | $P$-value | 95\% | Upper 95\% |
| Intercept | -51.66 | 26.54 | -1.95 | 0.0579 | -105.12 | 1.79877 |
| Obesity Rate | 133.10 | 179.02 | 0.74 | 0.461 | -227.46 | 493.652 |
| Per of Smokers | -135.76 | 111.63 | -1.22 | 0.230 | -360.58 | 89.07133 |
| Physical inactivity | 303.96 | 131.69 | 2.31 | 0.026 | 38.717 | 569.2072 |
| Hypertension | 716.10 | 165.77 | 4.32 | $\begin{gathered} \hline 8.5 \mathrm{E}- \\ 05 \\ \hline \end{gathered}$ | 382.22 | 1049.98 |
| Poverty | 112.58 | 103.19 | 1.10 | 0.281 | -95.26 | 320.4193 |

# Regression Analysis Project| Spring 2010 

By Xiaofeng Qian

So I calculated the sample autocorrelations between each pair of variables which are shown in Table 2. From Table 2, I found there are high correlations among the variables of the obesity rate, physical inactivity and hypertension rate ( $71 \%, 71 \%, 76 \%$ ).

Table 2. Correlations between pairs of variables

|  | H.D. Death <br> Rate | Obesity <br> Rate | Per of <br> Smokers | Physical <br> Inactivity | Hyper- <br> tension <br> Rate | Per below <br> Poverty |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Heart Disease Death <br> Rate/10^5(Y) | 1 | $68 \%$ | $49 \%$ | $77 \%$ | $84 \%$ | $59 \%$ |
| Obesity Rate | $68 \%$ | 1 | $59 \%$ | $71 \%$ | $71 \%$ | $51 \%$ |
| Percentage of <br> Smokers | $49 \%$ | $59 \%$ | 1 | $54 \%$ | $66 \%$ | $29 \%$ |
| No Leisure-Time <br> Physical Activity | $77 \%$ | $71 \%$ | $54 \%$ | 1 | $76 \%$ | $52 \%$ |
| Hypertension Rate <br> (\% Adults) | $84 \%$ | $71 \%$ | $66 \%$ | $76 \%$ | 1 | $58 \%$ |
| Percent below <br> Poverty | $59 \%$ | $51 \%$ | $29 \%$ | $52 \%$ | $58 \%$ | 1 |

Then I ran the regression models of the heart disease death rate over each variable ( the obesity rate, the physical inactivity and the hypertension rate) separately (Details seen in the attached excel spreadsheets). The comparison and summary of these statistics over the original multiple independent variable regression model (MVR) were displayed in Table 3. In comparison with the original multivariable model, all these three separated regression models have much stronger $F$ statistics, $t$ statistics and lower standard errors. It further confirms the existence of the multicollinearity in the original model. Although both the obesity rate and physical inactivity are good explanation of the variable of the heart disease death rate, I would remove them from my original model. Since the hypertension rate has a high correlation with these two variables $(71 \%, 76 \%)$ and the highest $F$ statistics, $t$ statistics and lowest standard error among these three variables, it would be a good reprehensive for the other two variables to explain the variable of the heart disease rate. A likely and intuitively explanation of this result is: Hypertension may directly cost heart disease. Most of fat or physical inactivity people may be easier to get a hypertension which leads to the heart disease.

# Regression Analysis Project $\mid$ Spring 2010 

By Xiaofeng Qian

The regression of the heart disease rate by state over the independent variables without obesity rate and physical inactivity was calculated and summarized in Table 4. Both R square and the adjusted R square are slightly decreased from the original model: R square is reduced from 0.766 to 0.724 ; the adjusted R square is reduced from 0.740 to 0.706 . But the F statistics is improved from original 29.5 to 41.1 . More importantly, the $t$ statistics is much more significant for the variables of hypertension and poverty rate now. The $t$ statistics for hypertension is raised from 4.32 to 6.64 and the $t$ statistics for the poverty rate is raised from 1.09 to 1.58 . However, the variable of percentage of smokers in the model is still not good. It has a high standard error/coefficient ratio $137 \%$ and $p$ value 0.47109 . Additionally, the percentage of smokers by state has a high correlation with hypertension rate by state ( $66 \%$ ) and low correlation with heart disease death rate ( $49 \%$ ). So I removed this variable from my model in the next step.

So our final regression model of the heart disease rate is built with only two independent variables: hypertension rate and poverty rate. The statistics data is shown in table 5 . The R square slightly decreases from 0.724 in previous model to 0.721 but the adjust $R$ square increases from 0.706 to 0.709 . Also $F$ statistics is improved from 41.1 to 62.0 in this model. The $t$ statistics is greatly enhanced as well. So in conclusion, I believed the final model is the best fit model with all these variables available. The equation will be:
$\mathrm{Y}_{\mathrm{i}}=-40.5+909.3 \times \mathrm{X}_{1 \mathrm{i}}+180.1 \times \mathrm{X}_{2 \mathrm{i}}$
where,
Y is the heart disease death rate / 100000 by state,
$\mathrm{X}_{1}$ is the hypertension rate by state,
$\mathrm{X}_{2}$ is the percentage below poverty by state.
The figure 1 shows the regression model predicts the Y variable pretty well.
